Studies in the rat indicate that both age and chronic ethanol intake cause a significant increase in renal clearance of titratable acids. We now propose to confirm this relationship in older, alcohol consuming man using an aminoacid- infusion paradigm. Studies are also designed to test the hypothesis that aging and chronic ethanol consumption affect other aspects of renal function such as renal handling of plasma glucose and other nitrogenous compounds. We propose to compare these renal functions in aged control rats with those from age-matched rats consuming moderate amounts of ethanol. Studies to investigate the effect of aging on acid-base status and renal function will be continued. The effect of aging on hepatic metabolism and renal functions will be studied with the use of the aminoacid infusion paradigm and diets varied in protein and aminoacid composition. The solution to the problem of choosing the optimal mix of planting density and nitrogen fertilizer in a soybean crop was found in Argentina. The new study, published in Plant Science, showed that extensive plantings of a reduced planting density coupled with the use of nitrogen fertilizer could markedly decrease contamination of soybeans by weed-suppressive soil microbes. The solution was based on current practice – planting soybean crops at high plant density with limited use of nitrogen fertilizer – but switching from granular to liquid nitrogen. “Planting soybeans at high density was traditionally recommended to reduce forage and weed competition, but this approach is inconvenient for farmers,” says lead researcher, Dr. Guillermo Serrano from INTA Chaco, Argentina. “Liquid fertilizer is less expensive, easier to distribute, and less polluting.” “The use of nitrogen fertilizer also increased the risk that the f678e9f9e
